

D08. PL/SQL Logic Pack

Overview

The PL/SQL Logic Pack contains one simple function that calculates how many available storage slots remain for a given warehouse location. It connects directly to the warehouse placement process because a location should not receive another pallet if it has no available capacity.

Function Used

The function is called `GET_LOCATION_AVAILABLE_SLOTS`. It receives a `LOCATION_ID` and returns the remaining capacity for that location.

The calculation is:

`available slots = capacity - used_slots - assigned pallets`

The function uses the real FlowCore tables. It reads `CAPACITY` and `USED_SLOTS` from `LOCATION`, and it counts the pallets assigned to the same location from `PALLET`.

Run Instructions

The `PLSQL_SQL_Logic.sql` file must be run after the `MySchema.sql` and `Sample_Data.sql` files.

Expected Results With The Current Configuration

- **A01: capacity 1, one assigned pallet, expected available slots 0.**
- **A02: capacity 1, one assigned pallet, expected available slots 0.**
- **A03: capacity 1, one assigned pallet, expected available slots 0.**
- **B01: capacity 2, no assigned pallets, expected available slots 2.**
- **C01: capacity 1, no assigned pallets, expected available slots 1.**
